According to the World Health Organization (WHO), violence against women (VAW) is a widespread experience worldwide with serious public health implications of epidemic proportions. Intimate Partner Violence (IPV) is the most common form of violence against women, and sexual violence, whether by partners, acquaintances or strangers, affects primarily women and girls. Other forms of violence against women include sexual harassment and abuse by authority figures, trafficking for forced labor or sex, and traditional practices such as forced or child marriages and dowry-related violence. Violence against women is often related to social and gender bias and, at its most extreme, may lead to violent death or female infanticide.

A HEALTH PROBLEM THAT'S GLOBAL
The consequences of this human rights violation bring major problems, not only for the woman, but also for the family, the community and the world. For the community, VAW remains a hidden problem with great human and health-care costs as a result of underreporting. For each victim, VAW leads not only to bodily injury but also has serious health consequences that can lead to life-long disability or even death.³

Makila is one of 1,260 girls in Congo who die after undergoing genital mutilation each year. Thousands more will suffer infertility or horrible physical deformities that render them outcasts, living in pain for years.

Nancy was raped by her mother’s abusive boyfriend; this type of abuse occurs on average every 17 hours in the United States. Nancy—like thousands of other girls who have been abused—will suffer health problems throughout her life because of this trauma.

Abuse against women and girls causes physical health problems far beyond the primary or most obvious scars, either physical or psychological. Results of abuse will impact victims’ health for years. Violence against women is truly a public health concern.

HEALTH CONSEQUENCES OF VIOLENCE AGAINST WOMEN AND GIRLS

1. Makila is one of 1,260 girls in Congo who die after undergoing genital mutilation each year. Thousands more will suffer infertility or horrible physical deformities that render them outcasts, living in pain for years.

2. Nancy was raped by her mother’s abusive boyfriend; this type of abuse occurs on average every 17 hours in the United States. Nancy—like thousands of other girls who have been abused—will suffer health problems throughout her life because of this trauma.

3. Abuse against women and girls causes physical health problems far beyond the primary or most obvious scars, either physical or psychological. Results of abuse will impact victims’ health for years. Violence against women is truly a public health concern.

In adult women, violence can lead to many health problems related to stress-induced physiological changes. Some are related to cardiovascular or metabolic problems that result from the chronic stress response that the body is subjected to. Other problems may include substance use, or lack of fertility control and personal autonomy as often seen in abusive relationships.

HEALTH CONSEQUENCES FOR WOMEN

We know that compared to their non-abused peers, abused women have higher rates of reproductive problems such as:
- unintended pregnancies
- abortions
- adverse pregnancies and neonatal and infant outcomes
- sexually transmitted infections (including HIV/AIDS)

Intimate Partner Violence (IPV) is the most common form of violence against women. A WHO study in 11 countries found that between 15% and 71% of women (depending on the country) who experienced physical or sexual violence by a husband or partner in their lifetime, had:
- high blood pressure
- high blood glucose
- overweight and obesity
- high cholesterol
- depression
- alcohol and substance abuse
- PTSD
- suicidal ideas and actions

These conditions often limit the ability of women to manage other chronic illnesses such as diabetes and hypertension.

FATALITIES: Intimate Partner violence may also be fatal. Studies from several countries (Australia, Canada, Israel, South Africa and the United States) found that nearly half of children in the study had been exposed to at least one incident of mild or severe violence in the family. Another study shows that fifty percent (50%) of men who frequently assault their wives frequently assault their children also, and the U.S. Advisory Board on Child Abuse and Neglect suggests that domestic violence is likely the single major precursor to child abuse and neglect fatalities. In the United States, an important group of studies shows the link between adverse childhood experiences (ACE) such as abuse, neglect, and witnessed abuse, to negative physical and mental health outcomes later in adulthood.

Compared to kids with no abuse history, kids exposed to abuse had higher risk for:
- cardiovascular disease
- type 2 diabetes
- dysregulated immune system
- substance abuse
- depression
- anxiety
- cancer
- suicide attempts
- drug and alcohol abuse
- gastrointestinal problems

Also noted in US studies were changes in brain structure, such as evidence of smaller frontal lobes, negative psychological consequences and poor mental health outcomes which further influence the body’s stress load, impacting the physical health and quality of life of the trauma survivor. Victims and child witnesses of violence often experience fear, shame, guilt, and stigma. These negative emotions contribute to severe burdens of mental and emotional problems, particularly depression and post traumatic stress disorder (PTSD) as noted above.

WITNESSING DOMESTIC VIOLENCE

Witnessed abuse is considered by some as serious child abuse. Certainly, the physical and mental health consequences do testify to that. Children who witness domestic violence are more likely to exhibit behavioral and physical health problems including:
- depression
- anxiety
- suicide attempts
- drug and alcohol abuse
- posttraumatic stress disorder
- headache (such as bed-wetting or nightmares)
- flu

HEALTH CONSEQUENCES DURING PREGNANCY

Among pregnant women with a history of abuse, there is a significantly higher rate of complications during pregnancy, such as:
- low weight gain
- anemia
- infections
- first and second trimester bleeding
- depression
- suicidal tendencies
- use of tobacco and/or alcohol
- illicit drug use

Worldwide, child abuse has both immediate and long-term consequences for the health of women and contributes significantly to:
- depression
- alcohol and drug use and dependence
- panic disorder
- post-traumatic stress disorder
- suicide attempts

HARM TO CHILDREN

In the US, a study of low-income pre-school children in Michigan found that nearly half (46.7%) of the children in the study had been exposed to at least one incident of mild or severe

In adult women, violence can lead to many health problems related to stress-induced physiological changes. Some are related to cardiovascular or metabolic problems that result from the chronic stress response that the body is subjected to. Other problems may include substance use, or lack of fertility control and personal autonomy as often seen in abusive relationships.

HEALTH CONSEQUENCES FOR GIRLS

Prevalence of child abuse also has epidemic proportions. Many children of both sexes suffer from physical and emotional maltreatment, sexual abuse, neglect, and commercial or other exploitation. According to the WHO, the evidence available indicates that girls are far more likely than boys to suffer sexual abuse.
